

SECUREBOX

Portable Adaptive Security Gateway, Zero-Trust Workspace & Enterprise BYOD Platform

Document Type: Product Concept / Technical Architecture / Project Documentation

Version: 1.0

Status: Concept / Prototype Planning

1. Executive Summary

SecureBox is a portable hardware cybersecurity device designed to provide a secure computing environment without requiring users to install complicated security software on their computers.

The device combines two major capabilities:

1. Personal network protection

- Protects laptops, phones and tablets when connected to public or untrusted networks.
- Provides secure VPN connectivity.
- Provides firewall protection.
- Detects suspicious networks and network attacks.
- Provides DNS security.
- Isolates the user's devices from other devices on the public network.

2. Enterprise secure workspace

- Allows employees to use their own Windows, Mac, Chromebook or other compatible devices.
- Provides access to a company-controlled virtual workspace.
- Allows a Mac user to work in a Windows environment without installing Windows locally.
- Keeps sensitive company data in the controlled corporate/cloud environment rather than storing it locally whenever the selected workspace policy supports this.
- Allows companies to reduce dependence on issuing dedicated laptops for every employee.

The core product philosophy is:

Plug in. Connect. Authenticate. Work securely.

The device acts as a hardware-based trust anchor between the user's physical device, the network and the company's protected environment.

2. Problem Statement

Modern employees work from:

- Home
- Offices
- Hotels
- Airports
- Cafés
- Coworking spaces
- Customer locations
- Public Wi-Fi
- Personal laptops
- Corporate laptops
- Mac computers
- Windows computers
- Tablets and mobile devices

This creates two major problems.

Problem A — Unsafe networks

Public networks can expose users to:

- Rogue access points
- Evil-twin networks
- ARP spoofing
- DNS manipulation
- Network scanning
- Unauthorized local-network communication
- Malicious devices
- Untrusted gateways
- Other network-level attacks

A normal VPN protects some communications but does not automatically provide complete endpoint security.

Problem B — Enterprise BYOD

Companies increasingly allow employees to use personal computers.

However, companies don't want confidential information copied onto unmanaged personal devices.

Traditional approaches can require:

- Company laptops
- Endpoint security agents
- VPN applications
- MDM
- VDI clients
- DLP software
- Multiple security applications
- IT configuration

This can be complicated for both employees and IT departments.
